Abstract

There are large between- and within-country variations in COVID-19 death rates. Some very low death rate settings such as Eastern Asia, Central Europe, the Balkans and Africa have a common feature of eating large quantities of fermented foods whose intake is associated with the activation of the Nrf2 (Nuclear factor (erythroid-derived 2)-like 2) anti-oxidant transcription factor. There are many Nrf2-interacting nutrients (berberine, curcumin, epigallocatechin gallate, genistein, quercetin, resveratrol, sulforaphane) that all act similarly to reduce insulin resistance, endothelial damage, lung injury and cytokine storm. They also act on the same mechanisms (mTOR: Mammalian target of rapamycin, PPARγ: Peroxisome proliferator-activated receptor, NFκB: Nuclear factor kappa B, ERK: Extracellular signal-regulated kinases and eIF2α: Elongation initiation factor 2α). They may as a result be important in mitigating the severity of COVID-19, acting through the endoplasmic reticulum stress or ACE-Angiotensin-II-AT1R axis (AT1R) pathway. Interestingly, geographical areas with very low COVID-19 mortality are those with the lowest prevalence of obesity (Sub-Saharan Africa and Asia). It is tempting to propose that Nrf2-interacting foods and nutrients can re-balance insulin resistance and have a significant effect on COVID-19 severity. It is therefore possible that the intake of these foods may restore an optimal natural balance for the Nrf2 pathway and may be of interest in the mitigation of COVID-19 severity.

Abbreviations

ACE: Angiotensin converting enzyme
AKT: Protein kinase B
Ang II: Angiotensin II
AT1R: Angiotensin II receptor type 1
COVID-19: Coronavirus 19 disease
DNA: Desoxyribonucleic acid
EGCG: Epigallocatechin gallate
eIF2α: Elongation initiation factor 2α
ER: Endoplasmic reticulum
ERK: Extracellular signal-regulated kinases
GI: Gastro-intestinal
HCV: Hepatitis C virus
HIV: Human immunodeficiency virus
IFN: Interferon
IR: Insulin resistance
Keap1: Kelch-like ECH-associated protein 1
LAB: Lactic acid bacilli
mTOR: Mammalian target of rapamycin
mTORC: mTOR complex
MAPK: Mitogen-activated protein kinases
NADPH: Nicotinamide adenine dinucleotide phosphate
NF-κB: Nuclear factor kappa B
Nox: NADPH oxidase
Nrf2: Nuclear factor (erythroid-derived 2)-like 2
PI3K: Phosphoinositide 3-kinase
PPAR: Peroxisome proliferator-activated receptor
PERK: Protein kinase R (PKR)-like endoplasmic reticulum kinase
PKR: protein kinase R
RAAS: Renin-Angiotensin-Aldosterone system
ROS: Reactive oxygen species
RSV: Respiratory syncytial virus
SARS: Severe acute respiratory syndrome
SARS-Cov-2: Severe acute respiratory syndrome coronavirus 2
STING: Signalling effector stimulator of interferon genes
T2D: Type 2 diabetes
UPR: Unfolded protein response

Key words: COVID-19, Nrf2, foods, nutrients, insulin resistance, obesity
Introduction

Large differences in COVID-19 death rates exist between countries and between regions of the same country. Some very low death rate geographical areas such as Eastern Asia, Central Europe, the Balkans and Africa have a common feature: the consumption of large quantities of fermented foods (1-3) in which lactic acid bacteria are important. Notwithstanding the fact that data from ecological studies need to be interpreted with caution, fermented vegetables or cabbage have been found to be associated with low COVID-19 death rates in European countries (3-5).

Reactive oxygen species (ROS) exert beneficial and toxic effects on cellular functions. Nrf2 is a pleiotropic transcription factor protecting against oxidative stress. It expresses a wide array of genes involved in immunity and inflammation, including antiviral actions (6). Several Nrf2-interacting natural compounds (e.g. berberine, curcumin, epigallocatechin gallate, genistein, quercetin, resveratrol, sulfaphane) and lactobacilli acting as antioxidants are effective against insulin resistance associated diseases (7). They may be important in the mitigation of COVID-19 (3, 7, 8), acting through the endoplasmic reticulum (ER) (9-11) or ACE-Angiotensin-II-AT$_1$R axis (AT$_1$R) pathway (2, 3) and leading to insulin resistance (IR), endothelial damage, lung injury and cytokine storm. They may also interact with SARS-CoV-2 by other pathways involved in IR that may be Nrf2-dependent or independent (9-11).

Obesity is a very important risk factor for COVID-19 severity (12) and is often associated with diet. There may be interactions between obesity, diet and COVID-19, possibly linked with Nrf2 (13).

The present rostrum follows the first two papers on diet and COVID-19 (2, 3). Specifically, we seek to (i) expand discussion on the role of Nrf2-interacting natural nutrients in IR, (ii) assess the mechanisms on ER stress and the AT$_1$R pathway, and (iii) understand how Nrf2-interacting nutrients can interplay to mitigate COVID-19.

1- Nrf2-interacting nutrients

The most common Nrf2 nutrients include berberine, curcumin, epigallocatechin gallate (EGCG), genistein, quercetin, resveratrol, sulfaphane mostly found in vegetables and fruits, and *Lactobacillus* in fermented foods (Table 1).

EGCG: Epigallocatechin gallate,

**Herbs, fruits or vegetables** such as garlic (14) or kiwi can also have antioxidant activities mediated by Nrf2 (7).

**Micronutrients** such as Zinc, Chromium, Selenium (15) and vitamin D (16) possess antioxidant activities associated, at least partly, with activation of Nrf2.

### 2- Cellular response to SARS-CoV-2

#### 2-1- Endoplasmic reticulum stress response and Coronavirus

The coronavirus infection triggers ER stress responses in infected cells associated with increased levels of reactive oxygen species (ROS) and unfolded protein response (UPR) (17-19). As a general response, ER stress leads to PERK phosphorylation of the elongation initiation factor 2α (eIF2α) and of Nrf2 (20). Activated PERK inactivates eIF2α, leading to a decrease in overall protein synthesis. Phosphorylation of PKR and PERK has been observed in SARS-CoV-2-infected cells (21). ERK/MAPK and PI3K/AKT/mTOR signalling responses play important roles in Middle East respiratory syndrome coronavirus (MERS-CoV) infection (22). The key role in the synthesis of proteins essential for these mechanisms belongs to mTOR (mammalian target of rapamycin) complexes and signalling pathways involved in mTOR regulation including eIF2α (23). mTOR is a serine/threonine protein kinase in the PI3K-related kinase (PIKK) family that forms the catalytic subunit of two distinct protein complexes, known as mTOR Complex 1 (mTORC1) and 2 (mTORC2). The mTOR pathway functions as a central regulator of cell metabolism, growth, proliferation, and survival. mTORC1 mainly functions as a nutrient/energy/redox sensor and controls protein synthesis, lipid metabolism, and organelle biogenesis (24). mTORC2 promotes the activation of insulin receptors and insulin-like growth factor 1 receptors. mTORC1 and C2 complexes are activated by nutrients, growth factors, and inflammatory mediators.

ER stress and sustained UPR signalling are major contributors to the pathogenesis of several diseases, including inflammatory disorders and viral infections (25) and can increase the severity of these events (26). ER stress has an important role in cardiovascular and metabolic disease, obesity and in diabetes (27, 28) and pancreatic β-cell dysfunction, often through mTOR (29). Oxidative stress is counter-balanced by complex antioxidant defence systems regulated by a series of multiple pathways, including the UPR, to ensure that the response to oxidants is adequate. Nrf2, interrelated with the UPR sensor called the pancreatic endoplasmic reticulum kinase, is a regulator of cellular resistance to oxidants (20, 30).

A recent study showed a disruption of mTOR signalling with increased levels of mTOR and a down-regulation of eIF2 signalling in multiple cellular compartments of severe COVID-19 patients when compared to patients who recovered (31).

#### 2-2- AT1R-associated effects

Angiotensin II (AngII) is the predominant Renin-Angiotensin-Aldosterone system (RAAS) component contributing to IR (32). The angiotensin-converting enzyme 2 (ACE2) receptor is part of the dual RAAS system consisting of an AT1R axis and an ACE-2-Angiotensin-(1-7)-Mas axis. AT1R is involved in most of the effects of Ang II, including oxidative stress generation (33), which in turn upregulates AT1R (34).
In metabolic disorders and with older age, there is an upregulation of the AT\(_1\)R axis leading to pro-inflammatory, pro-fibrotic effects in the respiratory system, endothelial damage and IR (35). SARS-CoV-2 binds to its receptor ACE2 and exploits it for entry into the cell. The ACE2 downregulation, as a result of SARS-CoV-2 binding, enhances the AT\(_1\)R axis (36) likely to be associated with IR (37, 38), but also with inflammation (39) and severe outcomes of COVID-19. Nrf2 is the most potent antioxidant in humans and can block the AT\(_1\)R axis (6).

2-3 Cross-talk between the renin-angiotensin-aldosterone system (RAAS) and endoplasmic reticulum (Figure 1)

Several studies have shown an interaction of RAAS and ER in insulin resistance. Ang-II increases ER stress in adipose tissue (40). ACE2 regulates intramuscular fat by improving ER and mitochondrial function (41). On the other hand, Ang 1-7 protects against Ang II-induced ER stress and endothelial dysfunction via the Mas receptor (42). These mechanisms appear to be of great importance in COVID-19 and propose an interaction between ER stress and AT\(_1\)R/Mas pathways with Nrf2 at the centre of the regulatory mechanism.

Moreover, in addition to reducing the production of infectious virions, the inhibition of ER glucosidases also impairs the entry of selected viruses via a post-receptor-binding mechanism (43).

2-4 Nrf2 in cytokine storm, endothelium and lung damage

The Nrf2 signalling pathway regulates anti-inflammatory gene expression and inhibits the progression of inflammation (44). In particular, the upregulation of Nrf2 signalling inhibits the overproduction of IL-6, pro-inflammatory cytokines, and chemokines as well as limiting the activation of NF\(\kappa\)B.

Failure to protect against oxidative stress-induced cellular damage leads to endothelial dysfunction in cardiovascular diseases and other pathologies associated with metabolic syndrome. Several antioxidant
pathways are involved in cellular redox homeostasis, among which the Nrf2 signalling pathway is one of the most prominent (45).

Nrf2 induces cellular rescue pathways against oxidative pulmonary injury, abnormal inflammatory and immune responses, as well as apoptosis. The Nrf2 pathway can protect against various lung injuries including acute lung injury and acute respiratory distress syndrome (46).

2.5. Complexity of the anti-oxidant response

It is clear that Nrf2 is only one mechanism of the anti-oxidant stress and that multiple products can act on the anti-oxidant stress of COVID-19. As an example, sulforaphane protects against acetaminophen-induced hepatotoxicity (47). Its anti-oxidant and anti-inflammatory activity may be enhanced in vitro by combining it with some medications used in COVID-19 such as acetaminophen (48).

3- Nrf2-interacting nutrients and COVID-19

Obesity, possibly hypertension, type 2 diabetes (T2D) and ageing all represent risk factors for severe COVID-19 associated with cytokine storm and IL-6, endothelial damage in different organs and lung damage.

IR is a pathological condition in which cells fail to respond normally to the hormone insulin. Major mechanisms of IR include oxidative stress, inflammation, insulin receptor mutations, endoplasmic reticulum stress, and mitochondrial dysfunction (49). In COVID-19, IR can be induced by at least ER stress or the AT1R pathways. IR is a key component of the metabolic syndrome, a clustering of at least three of the five following medical conditions: abdominal obesity (50), high blood pressure (51), high blood sugar, high serum triglycerides, and low serum high-density lipoprotein (HDL) (52). The metabolic syndrome is associated with the risk of developing cardiovascular disease and T2D (53, 54). All nine Nrf2-interacting nutrients had some effect – although sometimes weak – against obesity, hypertension and T2D (Table 2).

Table 2: Effect of Nrf2-interacting nutrients on diseases associated with oxidative stress

| Search strategy: For this table, in order to compare the mechanisms of action and properties of Nrf2-interacting nutrients, a PubMed search was initiated. This was not a systematic review, but an attempt to assess whether the impact on the disease has been described. 1. We searched PubMed using the display option “best matches”. 2. We first searched “systematic reviews” by PubMed for the different nutrients and we collected the first “best match” systematic review related to the question. 3. If there was no systematic review, we searched for “reviews” and we collected the first “best match” review related to the question. 4. If there was no review, we searched for papers and we collected the first “best match” paper related to the question. |

IR is frequently associated with endothelial dysfunction and has been proposed to play a major role in cardiovascular (107), kidney (108) or cerebrovascular diseases (109). All nine Nrf2-interacting nutrients had an effect against endothelial damage.

Ageing is associated with IR (110) and all nine Nrf2-interacting nutrients had an effect on ageing. All nine Nrf2-interacting nutrients reduce IL-6 and cytokines.

4- Mechanisms of Nrf2-interacting nutrients in COVID-19

Most Nrf2-interacting nutrients have an action on mTOR, PPARγ, NFκB, ERK and eIF2α (Table 3).

Berberine through NFκB and MAPK pathways has an anti-viral activity on several viruses, and potentially against SARS-CoV-2 (111). Curcumin can block the entry of viruses into cells or its replication in the cell (140). It acts on NFκB (169) or MAPK (170). EGCG has multiple antiviral properties possibly through MAPK (171).

The suppressive effects of EGCG on viral replication were abolished in cells with knocked-down Nrf2 expression (172). siRNA-mediated depletion of Nrf2 boosted HIV infectivity in primary macrophages and reduced the anti-viral effects of sulforaphane (173). In a murine model, RSV-induced bronchopulmonary inflammation, epithelial injury, and mucus cell metaplasia as well as nasal epithelial injury were significantly greater in Nrf2(-/-) mice than in Nrf2(+/+) mice. Sulforaphane pre-treatment significantly limited lung RSV replication and virus-induced inflammation in Nrf2(+/+) but not in Nrf2(-/-) mice. This effect may be mediated through NFκB (174). Sulforaphane through Nrf2 significantly suppressed the hepatitis C virus (HCV) protein and RNA levels in HCV replicon cells and infectious system (175). Caffeic acid could modulate Keap1/Nrf2 interaction via increasing p62 expression, leading to the stabilization of Nrf2 and HO-1 induction, and an elicit IFNα antiviral response to suppress HCV replication (176). HCV genome replication was also suppressed in HCV sub-genomic replicon-bearing cells by bardoxolone methyl (BARD), an Nrf2 activator (177).

Type I IFNs (IFNα and -β) are central to immune-protection against viral infection (178). A balanced production of type I IFNs is needed for the protection against virus, but excessive production is a potent driver of pathology (178). Intracellular DNA and RNA sensors are essential in the innate immune response to viruses, causing the secretion of type I IFNs, cytokines and chemokines from infected cells. Viral cytosolic DNA is recognized by DNA sensors such as cyclic GMP-AMP synthase (cGAS) and its downstream signalling effector stimulator of interferon genes (STING) (179). Sulforaphane through Nrf2 activation decreases STING expression and responsiveness to STING agonists while increasing susceptibility to infection with DNA viruses (168). Reduction of STING expression by Nrf2 is mechanistically distinct from how Nrf2 reduces the release of the pro-inflammatory cytokines IL-1β and IL-6 (168). Nrf2 negatively regulates Type I INF responses and increases susceptibility to herpes genital infection in mice (180). Itaconate is a crucial anti-inflammatory metabolite that acts via Nrf2 to limit inflammation and modulate type I IFNs (181).

### 4-2. mTOR and eIF2α

Several Nrf2-interacting nutrients act through mTOR or eIF2α. The insulin-sensitizing action of berberine was related to reducing ER stress in Hep G2 cells. The levels of phosphorylation both on PERK and eIF2α were inhibited in cells pretreated with berberine (112). In an IR animal model, curcumin was found to act on eIF2α (115). The induction of the ER stress pathway by green tea EGCG in colorectal cancer cells is mediated by the activation of PERK (182). The proteasome inhibitors Bortezomib (BZM) and MG132 trigger cancer cell death via induction of ER stress and UPR. EGCG antagonizes BZM toxicity by exacerbating the activation of autophagy and eIF2α up-regulation (119). In rats, genistein protects against acute pancreatitis via the activation of an apoptotic pathway mediated through activation of multiple ER stress-related regulators like GRP78, PERK, and eIF2α (125). Quercetin blocks airway epithelial cell chemokine expression though eIF2α phosphorylation (133).
Pterostilbene (PT), a natural analogue of resveratrol, inhibits hepatocellular cell (HCC) growth without the induction of apoptosis in an ER stress- and autophagy-dependent manner through the eIF2α pathway (135). Resveratrol modulates response against acute inflammatory stimuli in aged mouse brain. ER stress markers demonstrated significant changes in resveratrol-treated mice after LPS treatment, specifically in eIF2α (183). Other studies have found an effect of resveratrol on eIF2α (184, 185).

Sulforaphane exerts a neuroprotective effect involving Nrf2-dependent reductions in oxidative stress, mTOR-dependent inhibition of neuronal apoptosis, and the restoration of normal autophagy (186). Sulforaphane also inhibits mTOR in an Nrf2-independent manner (136).

Kimchi attenuates fatty streak formation in the aorta of low-density lipoprotein receptor knockout mice via the inhibition of ER stress (via several mechanisms including eIF2α) and apoptosis (187). Nutrients originating from Kimchi and its ingredients modulate the Nrf2/PERK signalling pathway to homeostasis in oxidative stress states. Kimchi and its bioactive compound ([3-4’-hydroxyl-3’,5’-dimethoxyphenyl] propionic acid: HDMPPA), which is a metabolite result from fermentation, alleviate oxidative stress and inflammatory response not only via the Nrf2 pathway, but also via the PERK/CHOP pathway, which induced apoptosis of ER, in cardiovascular disease and ageing models (188-190). In addition, Arvelexin from Brassica rapa and anthocyanin-rich extract from red cabbage exert anti-inflammatory properties by the inhibition of NF-κB activation and by Nrf2-regulated HO-1 induction in macrophages and apolipoprotein E-deficient mice (191, 192), suggesting that Nrf2 activation during inflammation antagonizes the NF-κB pathway. It is possible that the intake of Kimchi may help to mitigate COVID-19 outcomes by maintaining or restoring the Nrf2 system.

4-3- AT₁R

Curcumin (61), EGCG (71), genistein (77, 78) and resveratrol (96) impact the AT₁R pathway. NADPH oxidases of the Nox family are important sources of ROS and important agents in hypertension. They increase blood pressure in the presence of Ang II, an important and potent regulator of cardiovascular NADPH oxidase, via AT₁R. Several natural compounds such as berberine, curcumin, quercetine, resveratrol and others are Nox inhibitors (193). Dietary curcumin supplementation can increase antioxidant activity through the induction of heme oxygenase-1, a scavenger of free radicals, and through the reduction of reactive oxygen species and Nox-2 (194). Sulforaphane reduces Ang II-induced vascular smooth muscle cells through Nrf2 signalling (195).

5- Complex interactions in oxidative stress

IR induces oxidative stress either through the overproduction of superoxide by ER stress or the activation of Ang II-mediated upregulation of nicotinamide adenine dinucleotide phosphate (NADPH)-oxidase (NOX) activity, resulting in the cytosolic production of ROS (196) (Figure 2).
Figure 2: Complex interactions leading to oxidative stress in diabetes (from (196))

One of the key features of the complex interaction between nutrients and the oxidative stress/inflammatory response is the differential regulation of NFκB and Nrf2 by the cell redox status (197). Nrf2 and NFκB are present in an inactive form in the cytosol since they are linked to an inhibitory compound iNFκB or INrf2 (Keap 1), both targets of reactive oxygen species (198-200). In the case of a large production of ROS, which would overwhelm the antioxidant defence, iNFκB is oxidized and catabolized. Furthermore, NFκB is translocated to the nucleus and initiates the expression of inflammatory proteins such as cytokines, chemokines, adhesion molecules, cytokine receptors, iNOS, lipoxygenases, cyclooxygenases and growth factors …. (201, 202). Once produced, cytokines are able to activate oxidant production by the NADPH oxidase complex, leading to an oxidative burst, which could in turn enhance the NFκB activation. Thus, NFκB activation results in a directional and synergistic linkage of inflammation and oxidative stress (199, 203).

The canonical pathway of Nrf2 activation also involves changes in the cell redox state (189). A weak or controlled ROS production results in the degradation of Keap 1. Thus, Nrf-2 could be translocated to the nucleus, binds to the antioxidant response element and activates an antioxidant enzyme such as Heme Oxigenase, SOD and catalase or cytoprotective genes (204, 205). It could also reduce the production of ROS (206). The increase in antioxidant defence maintains or restores the cellular redox state. In addition, Nrf2 stimulation could downregulate NFkB activation (207, 208). In fact, redox signalling appears as a black box, controlling both NFκB and Nrf2 activation and thus regulating inflammation and reparation. It is now recognized that the regulation of both pathways, NFκB and Nrf2, in part linked to the redox status, involved a cross talk to bring a coordinated inflammatory response (209, 210). The intensity of the ROS insult could be a key factor in the imbalance of the NFκB/Nrf2 system (211). In the case of oxidative stress, stimulation of NFκB (associated with a degradation of both Keap 1 and Nrf2) results in an amplification loop of inflammation. Thus, an imbalance between the NFκB and Nrf2 pathways has already been observed in T2D (195) or in multiple sclerosis. By contrast, an active and effective anti-oxidant system could result in a preventive loop leading to anti-oxidative and anti-inflammatory response. In this context, a positive modulation of Nrf2 by nutrients could act as an « oxidative pre-conditioning » system, and the resulting increase in the antioxidant enzyme could attenuate ROS deleterious effects and maintain cell integrity (212, 213).
This black box redox system could be effective in respiratory infection, particularly in COVID-19 (201). Indeed, COVID-19 activates RAAS and induces ER stress, resulting in ROS production (32, 33), which could be further enhanced by risk factors such as obesity, diabetes, and hypertension (214-216). Interestingly, RAAS activation seems related to COVID infection severity (39). If the ROS production overwhelms antioxidant defence, a vicious circle linking oxidative stress and inflammation is initiated leading to a cytokine storm, as well as lung and endothelial injury. On the other hand, if Nrf2 is activated via nutrients, the antioxidant response could maintain or restore an adequate redox status. This would lead to an antioxidant and anti-inflammatory response resulting in a pauci-symptomatic infection. Interestingly, very recently, a similar effect on the Nrf2/NFkB balance via redox signalling was hypothesized via ozone therapy (217).

However, although the therapeutic potential of Nrf2 raised great hopes in the early 2010s (218), Nrf2 levels vary significantly depending on the physiological and pathological context. Thus, a properly timed and targeted manipulation of the Nrf2 pathway is critical for an effective treatment (219). Surprisingly, only one Nrf2-based treatment has been approved: dimethyl fumarate (220), not devoid of side effects (221, 222). This suggests that the balance is difficult to reach in drug development. Nrf2 overexpression may also be associated with diabetic nephropathy or retinopathy (196). Recently, well-designed clinical trials with bardoxolone, an Nrf2 antagonist, were cancelled or stopped due to safety concerns (223). The Nrf2 system plays an important role in the body's natural defence against hyperglycaemia-induced damage. However, this initial adaptive response to counteract the diabetes-driven oxidative stress appears to be short-lived, after which the Nrf2 system becomes overwhelmed under chronic glucose stimulation (196).

6- Obesity, diet, Nrf2 and COVID-19

In general, T2D and obesity prevalence are associated and the following has been stated by the NCD Risk Factor Collaboration (NCD-RisC) “The upsurge of T2D reflects the global obesity epidemic” (224). However, many countries in Sub-Saharan Africa or Eastern Asia have a very low obesity prevalence that is not necessarily associated with a low diabetes prevalence (Figure 3). These countries have the lowest obesity prevalence as well as the lowest COVID-19 death rates. Obesity is lower in Canada than in the US and this may partly explain differences in COVID-19 severity between these two countries. Obesity is high in South Africa, possibly explaining the higher death rate in this country than in other Sub-Saharan African countries.

Many factors can explain this diabetes/obesity paradox. Genetic differences between countries are clear. However, the RODAM (Research on Obesity & Diabetes among African Migrants) study used a unique approach of comparing Ghanaians resident in the Netherlands, Germany, UK and Ghana to unravel the causes of obesity and T2D among African migrants and non-migrants. It showed striking differences suggesting that environmental factors are of great importance. Globally, one in 10 individuals is affected by T2D. In migrants, there is a higher T2D prevalence, the age of onset is younger and complications are more severe. One of the main determinants of T2D is obesity, which also disproportionally affects migrants (225-228). In rural Ghanaians, most T2D is independent of obesity (229) (Figure 4). Differences in food preferences were found across study sites: (i) in rural Ghana, diet concentrated on starchy foods (“roots, tubers, and plantain” diet) including cassava, (ii) in urban Ghana, nutrition was dominated by animal-based products, and (iii) in Europe, diet was highly diverse (230). The “roots, tubers, and plantain” diet was directly associated with increased 10-year cardiovascular disease risk (231) but the relationship between diet and T2D was unclear (232). In the national Korean cohort, obesity (50.4%) and abdominal obesity (47.8%) are associated with diabetes (233).
In COVID-19, obesity is a more severe risk factor than T2D (234). There is a dose-dependent association of obesity with worse COVID-19 morbidity requiring hospitalization and intensive care and with mortality. This particularly applies to patients younger than 50 to 60 years of age (235). Obesity is an important independent risk factor for serious COVID-19 disease (236, 237). The association between BMI and COVID-19-related mortality was U-shaped, both in type 1 diabetes and in T2D (lowest risk for those with a BMI of 25·0-29·9 kg/m²) (238). These data suggest differences between these two features of the metabolic syndrome for COVID-19 severity.

**Figure 3: Prevalence of obesity, diabetes** (NCD Risk Factor Collaboration (NCD-RisC, http://ncdrisc.org) and the COVID-19 death rate (Johns Hopkins Coronavirus Resource Center, https://coronavirus.jhu.edu)
Nrf2 is also involved in complications of Type-1 diabetes (239). All nine Nrf2-interacting nutrients had an effect against obesity, often through IR (55, 56, 62, 63, 79, 84, 85, 102, 240, 241) (Table 2). In addition, Nrf2 may improve adipogenesis and adipocyte differentiation (242). Thus, diet may be important in the prevention/management of obesity and, at the same time, may reduce the impact of COVID-19.

7- Conclusions

Interestingly, all nutrients tested had a similar effect on IR, cytokine storm, lung injury and endothelial damage. They were all active on most of the tested Nrf2 pathways. These data strongly suggest a common mechanism of action for all nutrients. These effects appear to be highly conserved (243). However, we need to understand the differences between obesity and T2D in some countries with low obesity prevalence. These mechanisms may help to better appraise COVID-19 (Figure 5).

It is tempting to propose that Nrf2-interacting foods and nutrients can help re-balance IR, and that they can have a significant effect on COVID-19 severity, and possibly also on susceptibility to infection by SARS-CoV-2. It is therefore possible that an increasing intake of specific foods may achieve an optimal natural balance for the Nrf2 pathway, since COVID-19 death rates, used as a proxy of severity, are low or very low in some countries where Nrf2-interacting nutrients are largely used (Figure 5). Understanding the balance between Nrf2-interacting foods and nutrients would help to: (i) better understand the mechanisms of the oxidative stress in the IR diseases, (ii) develop optimal Nrf2-interacting nutrients and diets to reduce the prevalence and severity of IR diseases, (iii) optimize Nrf2 drug development and (iv) develop these strategies to mitigate COVID-19 severity.
There are still many unresolved questions requesting research on the time of onset of any efficacy of foods in COVID-19, the amount of the food to be administered and the interactions with the microbiome.
